ABSTRACT

A series of analogues of Amb639752, a novel diacylglycerol kinase (DGK) inhibitor recently discovered by us via virtual screening, have been tested. The compounds were evaluated as DGK inhibitors on α , θ , and ζ isoforms, and as antagonists on serotonin receptors. From these assays emerged two novel compounds, namely **11** and **20**, which with an IC₅₀ respectively of 1.6 and 1.8 μ M are the most potent inhibitors of DGK α discovered to date. Both compounds demonstrated the ability to restore apoptosis in a cellular model of X-linked lymphoproliferative disease as well as the capacity to reduce the migration of cancer cells, suggesting their potential utility in preventing metastasis. Finally, relying on experimental biological data, molecular modelling studies allow us to set a three-point pharmacophore model for DGK inhibitors.

Diacylglycerol kinase; kinase inhibitors; structure–activity relationship; enzyme assays; molecular modelling

1. Introduction

Diacylglycerol kinases (DGKs) are a large family of enzymes that share a common catalytic activity: the phosphorylation of diacylglycerol (DAG) to phosphatidic acid (PA). Remarkably, both the substrate (DAG) and the product (PA) of the DGK-catalysed reaction, are bioactive lipids that can act as second messengers¹. DGK activity consequently serves as a switch to simultaneously dampen DAG-mediated signals and boost PA-mediated signals². Ten mammalian DGK isoforms (α , β , γ , δ , ϵ , ζ , η , θ , ι , and κ) have been identified and divided into five groups (type I–V) according to their structural features^{3,4}. The expression of these isoforms varies depending on the cell type. Among the 10 isoforms, the α isoform is among the most studied and characterised. This kinase is highly expressed in the brain, spleen, and thymus and, along with θ isoform, in the bone marrow. This enzyme is also highly expressed in T-lymphocytes, where it acts together with DGK ζ as negative regulator of the T-cell receptor (TCR) response, and a mediator of IL-2 mediated proliferation^{3,5}. The biological relevance of DGK α is best demonstrated in patients with X-linked lymphoproliferative disease (XLP-1), who experience life-threatening, uncontrolled accumulation of CD8⁺ T cells in response to the Epstein–Barr virus (EBV) infection⁶. In those patients, germline mutations of the adaptor protein SAP (SH2D1A) perturb TCR signalling and render DGK α constitutively active⁷. Deregulated DGK α activity renders

patient-derived lymphocytes resistant to reactivation-induced cell death (RICD). Thus, antigen-activated lymphocytes accumulate in lymphonodes and liver, resulting in severe immunopathology⁸. Importantly, DGK α inhibitors restore RICD sensitivity *in vitro* and *in vivo*, thus avoiding immunopathology and suggesting a putative therapeutic use of those molecules in XLP-1⁹.

Apart from T-cell regulation, DGK α also plays a role in cancer, mediating numerous aspects of cancer cell progression including survival^{10,11}, migration and invasion of cancer cells^{12–14}. In particular, it has been reported that DGK α is over expressed in hepatocellular carcinoma¹⁵, and melanoma cells¹¹ while other reports suggested that the growth of colon and breast cancer cell lines was significantly inhibited by DGK α -siRNA¹⁶ and DGK α /atypical PKC/ β 1 integrin signalling pathway was crucial for matrix invasion of breast carcinoma cells¹⁷. In addition, expression is also higher in lymphonodal metastasis than in breast and gastric original tumour^{18,19}. Finally, knock down of DGK α impairs glioblastoma tumorigenesis^{20,21}.

For all these reasons, the identification of strong and selective DGK α inhibitors, it is an important field of research. To date, only a handful of two-digit micromolar inhibitors of DGK α have been identified, but only three were the most characterised, namely, R59949, R59022, and ritanserin (Figure 1).

In our assay system, R59949 and R59022 have an IC₅₀ of 11 and 20 μ M, respectively⁹. Their efficacy has been evaluated *in vivo*

studies on mice, and is limited by their rapid clearance ($t_{1/2} \sim 2$ h)²². Furthermore, these two inhibitors are also able to target different isoforms of DGK, in particular R59022 acts on type III and V (ϵ e θ), while R59949 on type I and II (γ , δ e κ)^{23,24} and a study conducted by Boroda et al. recently demonstrated their strong antagonistic activity on 5-HT₂ receptors (R59022 IC₅₀ 5HT_{2A}=2.2 nM; R5994 IC₅₀ 5HT_{2A}=9.2 nM)²⁵.

A search on ChEMBL database²⁶ (<https://www.ebi.ac.uk/chembl/>) show how these two molecules have activity at the same range of concentration with other biological targets, behaving like a sort of promiscuous ligands. Ritanserin, a well-known serotonergic antagonist, is structurally similar to R59022, differing for an H-F isosteric substitution on a phenyl ring. Despite this small modification, Boroda et al. showed that ritanserin was a DGK α inhibitor (IC₅₀=15 μ M) more potent than R59022 and R59949 and with a better pharmacokinetic profile ($t_{1/2}$ =40 h in human)²⁵. However, the comparison of ritanserin IC₅₀ as serotonin antagonist and as DGK α inhibitor, 0.9 nM and 15,000 nM, respectively, reveal that ritanserin is much a powerful serotonin antagonist than a DGK inhibitor. In addition, ritanserin is also a potent inhibitor on dopaminergic receptors with an IC₅₀ of 69 nM²⁷.

Due to these drawbacks, at the beginning, in order to eliminate the strong serotonergic activity of R59949, we reasoned to replace its protonable nitrogen atom, which at physiologically pH mimics the amino group of serotonin, with a carbon atom. We decided therefore to synthesise compound **1** (Figure 2) (see supporting information for its synthesis and a complete characterisation) and to test it as DGK α inhibitor.

Interestingly, the compound was totally devoid of inhibitory activity on the enzyme, showing the importance of the basic nitrogen atom not only for the anti-serotonergic activity, but also for the interaction with the kinase. With this in mind, we recently used an in-silico approach based on chemical homology with the two commercially available DGK α inhibitors R59022 and R59949 using the programmes ROCS²⁸ and EON²⁹. From this study, we identified a compound, Amb639752 (Figure 2), featuring a lower IC₅₀ for DGK α than ritanserin (IC₅₀=17 μ M), a better selectivity for the α -isoform and devoid of anti-serotonergic activity. Along with CU-3, which features an IC₅₀ of 0.6 μ M on DGK α ³⁰ but contains a reactive Michael acceptor³¹, Amb639752 is the most effective pharmacological tool available to study DGK α ⁹. In this manuscript, we report the structure-activity studies on Amb639752 and, in combination with data on ritanserin, the generation of a pharmacophore model for this class of compounds, which could be useful for the identification of other potential DGK α inhibitors.

2. Methods

2.1. Chemistry procedures

Commercially available reagents and solvents were used without further purification. Toluene were distilled immediately before use

from Na/benzophenone under a slight positive atmosphere of dry nitrogen. Dichloromethane was dried by distillation from P₂O₅ and stored on activated molecular sieves (4 Å). When needed the reactions were performed in flame- or oven-dried glassware under a positive pressure of dry nitrogen. Melting points were determined in open glass capillary with a Stuart scientific SMP3 apparatus and are uncorrected. All compounds were checked by IR (FT-IR THERMO-NICOLET AVATAR), ¹H and ¹³C APT (JEOL ECP 300 MHz spectrometer), and mass spectrometry (Thermo Finnigan LCQ-deca XP-plus, San Jose, CA) equipped with an ESI source and an ion trap detector. Chemical shifts are reported in parts per million (ppm). Flash column chromatography was performed on silica gel (Merck Kieselgel 60, 230–400 mesh ASTM, Kenilworth, NJ). Thin layer chromatography (TLC) was carried out on 5 × 20 cm plates with a layer thickness of 0.25 mm (Merck Silica gel 60 F₂₅₄, Kenilworth, NJ). When necessary they were developed with KMnO₄ reagent. Purity of tested compounds was established by elemental analysis. Elemental analysis (C, H, N) of the target compounds is within $\pm 0.4\%$ of the calculated values, confirming $\geq 95\%$ purity.

2.1.1. Preparation of 2-chloro-1-(2,6-dimethyl-1H-indol-3-yl)ethan-1-one (**5**)

In a Schlenk tube, under nitrogen, 2,6-dimethyl-1H-indole (**3**) (0.20 g, 1.38 mmol, 1 eq) was dissolved in 4 mL of dichloroethane dry and 0.25 mL of DBU (1.66 mmol, 1.2 eq) were added. The resulting solution was heated at 90 °C. When reached this temperature, chloroacetyl chloride (**4**) (0.12 mL, 1.52 mmol, 1.1 eq) was added. The reaction was stirred for 30 min, then solvent was evaporated and the crude purified by column chromatography using PE/EtOAc 7:3 and PE/EtOAc 5:5 as eluants to give 270 mg of product as violet solid: yield 90%; m.p. 243.7–244.2 °C; ¹H NMR (300 MHz, DMSO-d₆) δ 11.88 (br s, NH), 7.85 (d, J = 7.9 Hz, 1H), 7.18 (s, 1H), 6.99 (d, J = 8.0 Hz, 1H), 4.89 (s, 2H), 2.68 (s, 3H), 2.39 (s, 3H). MS (ESI) m/z : 222 [M + H]⁺.

2.1.2. Preparation of tert-butyl 4-(2-(2,6-dimethyl-1H-indol-3-yl)-2-oxoethyl)piperazine-1-carboxylate (**6**)

Under nitrogen, 200 mg of **5** (0.90 mmol, 1 eq) was dissolved in toluene dry, then *N*-Boc-piperazine (0.17 g, 0.90 mmol, 1 eq), K₂CO₃ (0.32 g, 2.25 mmol, 2.5 eq), and KI (0.015 g, 0.09 mmol,

Figure 2. Structures of the deaza analogue of R59949 and Amb639752.

Figure 1. Three of the most studied DGK α inhibitors.

0.1 eq) were added. The reaction was heated at 80 °C overnight. Solvent was evaporated and the crude was purified by column chromatography using PE/EtOAc 4:6 and PE/EtOAc 2:8 as eluants to give 215 mg of product as yellow amorphous solid: yield 63%; ¹H NMR (300 MHz, CDCl₃) δ 8.52 (br s, NH), 7.77 (d, *J* = 8.2 Hz, 1H), 7.12 (s, 1H), 7.08 (d, *J* = 8.0 Hz, 1H), 3.79 (s, 2H), 3.47–3.43 (m, 6H), 2.75 (s, 3H), 2.64 (br s, 2H), 2.44 (s, 3H), 1.47 (s, 9H). IR (KBr): 3190, 2964, 1698, 1413, 1417, 1364, 1126, 806 $\nu_{\max}/\text{cm}^{-1}$. MS (ESI) *m/z*: 372 [M + H]⁺.

2.1.3. Preparation of 1-(2,6-dimethyl-1H-indol-3-yl)-2-(piperazin-1-yl)ethan-1-one (7)

Two hundred and fifteen milligrams of **6** (0.58 mmol, 1 eq) were dissolved in dichloromethane dry. The resulting solution was cooled at 0 °C and 0.69 mL of trifluoroacetic acid (9.28 mmol, 16 eq) was added. After 3 h, the reaction was worked up adding NaOH 2 M solution until pH = 12. Then, NaCl solid was added and the solution was extracted with THF (x2). The combined organic phases were dried on sodium sulphate. After evaporation of the solvent, the crude was purified by column chromatography using EtOAc/MeOH 9:1 and MeCN/NH₃ 9:1 as eluants to give 103 mg of the product as yellowish solid: yield: 65%; m.p.: 232.9–233.6 °C; ¹H NMR (300 MHz, DMSO-*d*₆) δ 11.79 (br s, NH), 7.85 (d, *J* = 7.9 Hz, 1H), 7.15 (s, 1H), 6.95 (d, *J* = 8.2 Hz, 1H), 3.83 (br s, 4H), 3.62 (s, 2H), 2.86 (br s, 4H), 2.67 (s, 3H), 2.38 (s, 3H); IR (KBr): 3446, 3181, 2813, 1634, 1455, 1330, 821 $\nu_{\max}/\text{cm}^{-1}$; MS (ESI) *m/z*: 272 [M + H]⁺.

2.1.4. General procedure for the synthesis of final compounds 8, 11–22

1-(2,6-Dimethyl-1H-indol-3-yl)-2-(piperazin-1-yl)ethan-1-one (**7**) (1 eq) was dissolved in dichloromethane dry. To the resulting solution EDCI (1 eq), TEA (2 eq), DMAP (0.1 eq) and the appropriate carboxylic acid (1 eq) were sequentially added. The reaction was stirred under nitrogen at room temperature overnight. Evaporation of the solvent gave a crude which was directly purified by column chromatography.

2.1.5. 2-(4-Benzoylpiperazin-1-yl)-1-(2,6-dimethyl-1H-indol-3-yl)ethan-1-one (8)

Yellow solid; yield 29%; column eluants: EtOAc, EtOAc/MeOH 9:1; m.p.: 213.8–214.3 °C. ¹H NMR (300 MHz, DMSO-*d*₆) δ 11.72 (br s, NH), 7.85 (d, *J* = 8.2 Hz, 1H), 7.46–7.40 (m, 5H), 7.15 (s, 1H), 6.96 (d, *J* = 7.9 Hz, 1H), 3.67 (br s, 4H), 3.18 (br s, 2H) 2.67 (s, 3H), 2.61–2.56 (m, 4H), 2.38 (s, 3H); ¹³C NMR (75 MHz, DMSO-*d*₆) δ 192.8, 169.5, 144.7, 136.5, 135.7, 131.5, 130.0, 129.0, 127.5, 125.1, 123.4, 121.2, 112.9, 111.6, 66.9, 53.2, 53.1, 21.7, 15.7; IR (KBr) 3189, 2990, 2828, 1609, 1446, 1282, 807 $\nu_{\max}/\text{cm}^{-1}$. MS (ESI) *m/z*: 374 [M–H]⁺. Anal. Calcd. for C₂₃H₂₅N₃O₂: C, 73.57; H, 6.71; N, 11.19; found C, 73.76; H, 6.94; N, 10.85.

2.1.6. 2-(4-(4-Chlorobenzoyl)piperazin-1-yl)-1-(2,6-dimethyl-1H-indol-3-yl)ethan-1-one (11)

Yellow solid; yield 33%; column eluants: EtOAc, EtOAc/MeOH 9:1; m.p.: 240.7–241.3 °C; ¹H NMR (300 MHz, DMSO-*d*₆) δ 11.70 (br s, NH), 7.85 (d, *J* = 7.9 Hz, 1H), 7.50 (br d, AA'XX', 2H), 7.42 (br d, AA'XX', 2H), 7.14 (s, 1H), 6.95 (d, *J* = 8.2 Hz, 1H), 3.67 (br s, 4H), 3.33 (br s), 2.67 (s, 3H), 2.61–2.56 (m, 4H), 2.38 (s, 3H); ¹³C NMR (75 MHz, DMSO-*d*₆) δ 193.17, 168.4, 144.8, 135.7, 135.2, 134.8,

131.5, 129.5, 129.1, 125.1, 123.5, 121.2, 112.7, 111.6, 53.14, 53.14, 52.9, 21.7, 15.7. IR (KBr): 3225, 2793, 2358, 1609, 1442, 1261, 864 $\nu_{\max}/\text{cm}^{-1}$. MS (ESI) *m/z*: 410 [M + H]⁺. Anal. Calcd. for C₂₃H₂₄ClN₃O₂: C, 67.39; H, 5.90; N, 10.25; found C, 67.11; H, 6.12; N, 10.54.

2.1.7. 1-(2,6-Dimethyl-1H-indol-3-yl)-2-(4-(4-methoxybenzoyl)piperazin-1-yl)ethan-1-one (12)

Yellow solid; yield 53%; column eluants: EtOAc, EtOAc/MeOH 9:1; m.p.: 219.9–220.8 °C; ¹H NMR (300 MHz, DMSO-*d*₆) δ 11.70 (br s, NH), 7.85 (d, *J* = 8.2 Hz, 1H), 7.38 (br d, AA'XX', 2H), 7.14 (s, 1H), 6.99–6.94 (m, 3H), 3.79 (br d, 3H), 3.67 (br s, 2H), 3.51 (br s, 4H) 2.67 (s, 3H), 2.58 (br s, 4H), 2.38 (s, 3H); ¹³C NMR (75 MHz, DMSO-*d*₆) δ 192.8, 169.5, 144.6, 136.5, 135.7, 131.5, 130.0, 129.0, 127.5, 125.1, 123.4, 121.2, 112.8, 111.6, 66.9, 55.8, 53.2, 53.1, 21.7, 15.7; IR (KBr): 3235, 3003, 2807, 1613, 1463, 1253, 977 $\nu_{\max}/\text{cm}^{-1}$; MS (ESI) *m/z*: 406 [M + H]⁺. Anal. Calcd. for C₂₄H₂₇N₃O₃: C, 71.09; H, 6.71; N, 10.36; found C, 71.10; H, 6.75; N, 10.32.

2.1.8. 4-(4-(2-(2,6-Dimethyl-1H-indol-3-yl)-2-oxoethyl)piperazine-1-carbonyl)benzotrile (13)

Yellow solid; yield 23%; column eluants: EtOAc, EtOAc/MeOH 9:1; m.p.: 243.9–244.8 °C. ¹H NMR (300 MHz, DMSO-*d*₆) δ 11.70 (br s, NH), 7.92–7.84 (m, 3H), 7.58 (br d, AA'XX', 2H), 7.15 (s, 1H), 6.96 (br d, 1H), 3.68 (br s, 4H), 3.29 (br s, 2H), 2.67 (s, 3H), 2.51 (br s, 4H), 2.38 (s, 3H); ¹³C NMR (75 MHz, DMSO-*d*₆) δ 192.5, 166.3, 143.2, 139.4, 134.1, 131.6, 129.9, 126.8, 123.5, 121.9, 119.6, 117.4, 111.2, 111.1, 110.1, 65.1, 51.7, 51.2, 20.1, 14.1; IR (KBr): 3410, 3254, 2816, 2790, 2233, 1609, 1454, 1291, 979 $\nu_{\max}/\text{cm}^{-1}$; MS (ESI) *m/z*: 401[M + H]⁺. Anal. Calcd. for C₂₄H₂₄N₄O₂: C, 71.98; H, 6.04; N, 13.99; found C, 72.13; H, 6.23; N, 14.08.

2.1.9. 1-(2,6-Dimethyl-1H-indol-3-yl)-2-(4-(thiophene-2-carbonyl)piperazin-1-yl)ethan-1-one (14)

Yellow solid; yield 29%; column eluants: EtOAc, EtOAc/MeOH 9:1; m.p.: 200.3–201.2 °C; ¹H NMR (300 MHz, DMSO-*d*₆) δ 11.74 (br s, NH), 7.86 (d, *J* = 8.2 Hz, 1H), 7.76 (br d, 1H), 7.41–7.40 (m, 1H), 7.15–7.10 (m, 2H), 6.96 (d, *J* = 8.2 Hz, 1H), 3.75–3.67 (m, 4H), 3.37 (br s, 2H) 2.68 (s, 3H), 2.62 (s, 4H), 2.38 (s, 3H); ¹³C NMR (75 MHz, DMSO-*d*₆) δ 192.8, 167.8, 144.7, 137.8, 135.7, 131.5, 130.0, 129.6, 127.7, 125.1, 124.1, 123.4, 121.2, 112.8, 111.6, 66.7, 53.3, 21.7, 15.7; IR (KBr): 3270, 2927, 2793, 1642, 1454, 1261, 809 $\nu_{\max}/\text{cm}^{-1}$; MS (ESI) *m/z*: 382[M + H]⁺; Anal. Calcd. for C₂₁H₂₃N₃O₂S: C, 66.12; H, 6.08; N, 11.01; found C, 66.23; H, 6.26; N, 10.93.

2.1.10. 1-(2,6-Dimethyl-1H-indol-3-yl)-2-(4-nicotinoylpiperazin-1-yl)ethan-1-one (15)

Yellow solid; yield 39%; column eluants: EtOAc, EtOAc/MeOH 9:1; m.p.: 216.2–216.8 °C; ¹H NMR (300 MHz, DMSO-*d*₆) δ 11.70 (br s, NH), 8.65–8.61 (m, 2H), 7.87–7.82 (m, 2H), 7.50–7.45 (m, 1H), 7.15 (s, 1H), 6.95 (br d, 1H), 3.68 (br s, 4H), 3.37 (br s, 2H), 2.67 (s, 3H), 2.56 (br s, 4H), 2.37 (s, 3H); ¹³C NMR (75 MHz, DMSO-*d*₆) δ 192.6, 167.2, 151.0, 148.1, 144.7, 135.7, 135.4, 132.3, 131.5, 125.1, 124.1, 123.5, 121.2, 116.2, 111.6, 66.7, 53.4, 52.9, 21.7, 15.7; IR (KBr): 3414, 3213, 2828, 1621, 1454, 1267, 1301, 817 $\nu_{\max}/\text{cm}^{-1}$; MS (ESI) *m/z*: 377 [M + H]⁺; Anal. Calcd. for C₂₂H₂₄N₄O₂: C, 70.19; H, 6.43; N, 14.88; found C, 70.21; H, 6.44; N, 14.73.

2.1.11. 1-(2,6-Dimethyl-1H-indol-3-yl)-2-(4-(2-methylbenzoyl)piperazin-1-yl)ethan-1-one (16)

Yellow solid; yield 41%; column eluants: EtOAc, EtOAc/MeOH 9:1; m.p.: 200.5–201.6 °C; ¹H NMR (300 MHz, DMSO-d₆) δ 11.70 (br s, NH), 7.85 (d, *J* = 8.2 Hz, 1H), 7.31–7.27 (m, 3H), 7.26–7.24 (m, 2H), 7.15 (d, 1H), 3.69 (br s, 2H), 3.34 (br s, 2H), 3.15 (br s, 2H), 2.67 (s, 3H), 2.51 (br s, 4H), 2.44 (s, 3H), 2.38 (s, 3H); ¹³C NMR (75 MHz, DMSO-d₆) δ 192.6, 169.0, 144.7, 135.7, 134.2, 131.8, 131.5, 130.7, 129.2, 126.4, 126.2, 123.4, 121.2, 112.8, 66.8, 53.5, 53.0, 46.8, 41.4, 21.7, 19.2, 15.7; IR (KBr): 3431, 3221, 2919, 2797, 1615, 1454, 1257, 748 ν_{max}/cm⁻¹; MS (ESI) *m/z*: 390 [M + H]⁺. Anal. Calcd. for C₂₄H₂₇N₃O₂: C, 74.01; H, 6.99; N, 10.79; found C, 74.01; H, 7.01; N, 10.63.

2.1.12. 1-(2,6-Dimethyl-1H-indol-3-yl)-2-(4-(3-methoxybenzoyl)piperazin-1-yl)ethan-1-one (17)

Yellow solid; yield 32%; column eluants: EtOAc, EtOAc/MeOH 9:1; m.p.: 209.8–210.4 °C; ¹H NMR (300 MHz, DMSO-d₆) δ 11.71 (br s, NH), 7.85 (d, *J* = 7.9 Hz, 1H), 7.34 (t, 1H), 7.15 (br s, 1H), 7.02–6.92 (m, 4H), 3.78 (s, 3H), 3.68 (br s, 3H), 3.35 (br s, 3H), 2.67 (br s, 7H), 2.38 (s, 3H); ¹³C NMR (75 MHz, DMSO-d₆) δ 192.7, 169.1, 159.7, 144.7, 137.9, 135.7, 131.5, 130.2, 125.1, 123.4, 121.2, 119.4, 115.7, 112.7, 111.6, 66.8, 55.8, 53.3, 53.11, 47.4, 21.7, 15.7; IR (KBr): 3131, 3049, 2944, 1651, 1455, 1292, 1130, 968 ν_{max}/cm⁻¹; MS (ESI) *m/z*: 406 [M + H]⁺. Anal. Calcd. for C₂₄H₂₇N₃O₃: C, 71.09; H, 6.71; N, 10.36; found C, 70.85; H, 6.45; N, 10.76.

2.1.13. 2-(4-(3,4-Difluorobenzoyl)piperazin-1-yl)-1-(2,6-dimethyl-1H-indol-3-yl)ethan-1-one (18)

Yellow solid; yield 27%; column eluants: EtOAc, EtOAc/MeOH 9:1; m.p.: 233.8–235.0 °C; ¹H NMR (300 MHz, DMSO-d₆) δ 11.71 (br s, NH), 7.85 (d, *J* = 7.9 Hz, 1H), 7.56–7.47 (m, 2H), 7.28 (br s, 1H), 7.15 (s, 1H), 6.96 (d, *J* = 7.9 Hz, 1H), 3.68 (br s, 2H), 3.33 (br s, 2H), 2.67 (s, 3H), 2.51 (br s, 6H), 2.38 (s, 3H); MS (ESI) *m/z*: 412 [M + H]⁺; IR (KBr): 3252, 2919, 2795, 1618, 1469, 1286, 1046, 980 ν_{max}/cm⁻¹; MS (ESI) 412 [M + H]⁺. Anal. Calcd. for C₂₃H₂₃F₂N₃O₂: C, 67.14; H, 5.63; N, 10.21; found C, 67.43; H, 5.79; N, 10.59.

2.1.14. 2-(4-(3-Chlorobenzoyl)piperazin-1-yl)-1-(2,6-dimethyl-1H-indol-3-yl)ethan-1-one (19)

Yellow solid; yield 32%; column eluants: EtOAc, EtOAc/MeOH 9:1; m.p.: 222.3–223.5 °C; ¹H NMR (300 MHz, CDCl₃) δ 9.42 (br s, NH), 7.71 (d, *J* = 7.9 Hz, 1H), 7.40–7.25 (m, 4H), 7.04 (d, *J* = 8.2 Hz, 2H), 3.85 (br s, 4H), 3.47 (br s, 2H), 2.80 (br s, 1H), 2.68 (br s, 6H), 2.40 (s, 3H); ¹³C NMR (75 MHz CDCl₃) δ 192.5, 169.0, 144.7, 137.5, 135.3, 134.7, 132.3, 130.0, 127.3, 125.2, 124.0, 123.7, 120.6, 112.8, 111.4, 67.0, 53.7, 53.7, 29.6, 21.5, 15.7; IR (KBr): 3264, 2916, 2795, 1646, 1454, 1256, 978, 809 ν_{max}/cm⁻¹; MS (ESI) *m/z*: 410 [M + H]⁺. Anal. Calcd. for C₂₃H₂₄ClN₃O₂: C, 67.39; H, 5.90; N, 10.25; found C, 67.38; H, 5.90; N, 10.24.

2.1.15. 1-(2,6-Dimethyl-1H-indol-3-yl)-2-(4-(4-methylbenzoyl)piperazin-1-yl)ethan-1-one (20)

Yellow solid; yield 48%; column eluants: EtOAc, EtOAc/MeOH 9:1; m.p.: 230.9–231.2 °C; ¹H NMR (300 MHz, DMSO-d₆) δ 11.71 (br s, NH), 7.86–7.82 (m, 1H), 7.31–7.23 (m, 4H), 7.15 (s, 1H), 6.96 (d, *J* = 7.9 Hz, 1H), 3.69 (br s, 2H), 3.35 (br s, 4H), 2.67 (s, 3H), 2.51. IR (KBr): 3228, 2915, 2792, 1607, 1454, 1260, 979 ν_{max}/cm⁻¹; MS (ESI)

m/z: 390 [M + H]⁺; Anal. Calcd. for C₂₄H₂₇N₃O₂: C, 74.01; H, 6.99; N, 10.79; found C, 74.12; H, 7.02; N, 10.79.

2.1.16. 2-(4-(Cyclopentanecarbonyl)piperazin-1-yl)-1-(2,6-dimethyl-1H-indol-3-yl)ethan-1-one (21)

Brown oil; yield 61%; column eluants: EtOAc, EtOAc/MeOH 9:1; ¹H NMR (300 MHz, CDCl₃) δ 9.00 (br s, NH), 7.73 (d, *J* = 8.2 Hz, 1H), 7.26 (br d, 1H), 7.12 (s, 1H), 7.05 (d, *J* = 8.2 Hz, 1H), 3.83 (s, 2H), 3.75 (br s, 2H), 3.63 (br s, 2H), 2.80–2.71 (m, 7H), 2.45 (s, 3H), 1.92–1.46 (m, 7H); IR (KBr): 3253, 2944, 2862, 1650, 1620, 1455, 1234, 957 ν_{max}/cm⁻¹; MS (ESI) *m/z*: 368 [M + H]⁺; Anal. Calcd. for C₂₂H₂₉N₃O₂: C, 71.90; H, 7.95; N, 11.43; found C, 72.23; H, 8.31; N, 11.32.

2.1.17. 1-(4-(2-(2,6-Dimethyl-1H-indol-3-yl)-2-oxoethyl)piperazin-1-yl)heptan-1-one (22)

Brown oil; yield 76%; column eluants: EtOAc, EtOAc/MeOH 9:1; ¹H NMR (300 MHz, CDCl₃) δ 10.25 (br s, NH), 7.68 (d, *J* = 8.2 Hz, 1H), 7.08 (s, 1H), 7.00 (d, *J* = 7.9 Hz, 1H), 3.83 (s, 2H), 3.73 (br s, 2H), 3.56 (br s, 2H), 2.77–2.71 (m, 3H), 2.62 (s, 3H), 2.38 (s, 3H), 2.32–2.27 (m, 5H), 1.59–1.54 (m, 2H), 1.26 (br s, 4H), 0.85 (br t, 3H); ¹³C NMR (75 MHz, CDCl₃) δ 191.7, 172.4, 145.4, 135.5, 132.1, 124.0, 123.6, 120.4, 112.4, 111.6, 66.2, 53.3, 53.1, 45.3, 41.2, 34.5, 31.6, 28.9, 25.0, 22.5, 21.5, 15.6, 14.1; IR (KBr): 2927, 2857, 1731, 1645, 1455, 1434, 1234, 668 ν_{max}/cm⁻¹; MS (ESI) *m/z*: 384 [M + H]⁺; Anal. Calcd. for C₂₃H₃₃N₃O₂: C, 72.03; H, 8.67; N, 10.96; found C, 72.03; H, 8.73; N, 11.21.

2.2. Cell lines

Madin-Darby canine kidney (MDCK) cells stably expressing One Strep Tag DGKα (OST-DGKα) were prepared by infecting MDCK cells with a vector expressing an inducible OST tagged DGKα constructs¹⁷. MDCK cells infected with empty vector were used as controls. MDCK cells were cultured in MEM (minimal essential medium) with 5% FBS (foetal bovine serum) and 1% antibiotic-antimycotic solution. Routinely, cells were splitted every 3–4 days with trypsin–EDTA 0.25% in standard 100 mm dishes.

Human embryonic kidney 293T cells (10 cm² plates) were cultured in RPMI with 10% FBS and 1% penicillin/streptomycin and cultures were maintained by splitting them for every 2–3 days using trypsin–EDTA 0.25%.

Michigan Cancer Foundation 7 (MCF7) cells were cultured in DMEM with 10% FBS + 1% penicillin/streptomycin and cultures were maintained by splitting them for every 2–3 days using trypsin–EDTA 0.25%.

2.3. Primary cells

PBL were isolated from healthy anonymous human donors by Ficoll-Paque PLUS (GE Healthcare, Chicago, IL) density gradient centrifugation, washed, and resuspended at 2 × 10⁶ cell/mL in RPMI-GlutaMAX containing 10% heat inactivated FCS, 2 mM glutamine, and 100 U/mL of penicillin and streptomycin. T cells were activated with 1 μg/mL anti-CD3 (UCHT1) and anti-CD28 (clone CD28.2) antibodies. After three days, activated T cells were washed and cultured in medium additionated of 100 IU/mL rhIL-2 (Peprotech, Rocky Hill, NJ) at 1.2 × 10⁶ cells/mL for ≥7 days by changing media for every 2–3 days.

Human monocytes were isolated from healthy anonymous human buffy coats (provided by the Transfusion Service of

Ospedale Maggiore della Carità, Novara, Italy) by the standard technique of dextran sedimentation and Histopaque (density = 1.077 g cm³, Sigma-Aldrich, Milano, Italy) gradient centrifugation (400×g, 30 min, room temperature) and recovered by fine suction at the interface, as described previously³². Purified monocytes populations were obtained by adhesion (90 min, 37 °C, 5% CO₂) in serum-free RPMI 1640 medium (Sigma-Aldrich, Milano, Italy) supplemented with 2 mM glutamine and antibiotics. Cell viability (trypan blue dye exclusion) was usually >98%.

2.4. Preparation of DGK α enriched homogenates

Large cultures of MDCK cells for enzyme preparation were done by plating 5 × 10⁶ cells in 245 mm² dishes. Once they reached nearly 70% confluence, cells were treated with doxycycline (1 µg/mL, two days). After two days of treatment, each plate was washed in cold PBS and cells homogenised in 5 mL of homogenate buffer (25 mM Hepes (pH 8), 20% glycerol, 135 mM NaCl, 5 mM ethylenediaminetetraacetic acid (EDTA), 1 mM ethylene glycol-bis-(beta-aminoethyl ether)-N,N,N',N'-tetraacetic acid (EGTA), 1 mM sodium orthovanadate, and protease inhibitor cocktail) for each dish. Cells were collected with a rubber scraper, homogenised by passing them through a 29G-needle syringe 20 times and stored in aliquots at -80 °C. Presence of OST-DGK α was confirmed by western blotting and enzyme assay, transduced DGK α has an activity >100 folds the endogenous DGK.

2.5. Preparation of DGK ζ and DGK θ enriched homogenates

293T cells were transiently transfected with indicated DGK isoform plasmid DNA using Lipofectamine 3000, Invitrogen (Carlsbad, CA). Forty eight hours after transfection, cells were harvested and homogenised with a 29G-needle using 500 µL of homogenate buffer for each dish and immediately stored in aliquots at -80 °C. Cells transfected with empty vector were used as controls, overexpressed DGK has an activity >50 folds the endogenous.

2.6. DGK assay

Essentially, the same procedure was followed as reported previously in Velnati et al.⁹ In brief, DGK activity was assayed by measuring initial velocities (5 min at 27 °C) in presence of saturating substrate concentrations. Reaction conditions: 0.9 µg/µL 1,2-dioleoyl-sn-glycerol, 5 mM ATP, 0.01 µCi/µL [³²P]-ATP, 1 mM sodium orthovanadate, 10 mM MgCl₂, 1.2 mM EGTA in 7.5 mM Hepes pH 8¹². Reaction mixture is assembled mixing enzyme (24.5 µL of homogenate), 100× inhibitor or DMSO (0.5 µL), 5× ATP solution (10 µL of 25 mM ATP, 0.05 µCi/µL [³²P]-ATP (Perkin-Elmer, Milan, Italy), 5 mM sodium orthovanadate, 50 mM MgCl₂), and 3.3× DAG solution (15 µL of 3 µg/µL 1,2-dioleoyl-sn-glycerol resuspended by sonication in 4 mM EGTA in 25 mM Hepes pH 8). The reaction was stopped after 5 min by adding 200 µL of freshly prepared 1 M HCl and lipid was extracted by adding 200 µL of CH₃OH:CHCl₃ 1:1 solution and vortexing for 1 min. The two phases were separated by centrifugation (12,000 RCF for 2 min). Twenty-five microlitres of the lower organic phase was spotted in small drops on silica TLC plates. TLC was run 10 cm and dried before radioactive signals were detected by GS-250 molecular imager and was quantified by quantity one (Bio-Rad, Hercules, CA) software assuring the absence of saturated spots.

Percentage residual activity was calculated as follows: (OST-DGK α homogenate with inhibitor – vector homogenate)/(OST-DGK α homogenate with DMSO – vector homogenate) × 100.

2.7. Superoxide anion (O²⁻) production

All the experiments were performed in triplicate using cells isolated from each single donor.

Monocytes (250,000 cells/well) were treated for 1 h with the indicated drugs (10 µM) with or without serotonin (1 µM). Then, cells were stimulated with phorbol 12-myristate 13-acetate (PMA; Sigma-Aldrich, Milano, Italy) 1 µM for 30 min. PMA is a well-known stimulus that induces a strong and significant respiratory burst via PKC activation³³. Superoxide anion production was then evaluated by the superoxide dismutase (SOD)-sensitive cytochrome C (CytC) reduction assay and expressed as nmoles CytC reduced/10⁶ cells/30 min, using an extinction coefficient of 21.1 mM. To avoid interference with spectrophotometrical recordings, cells were incubated with RPMI 1640 without phenol red, antibiotics, and FBS.

2.8. RICD assay in SAP silenced T cells

Activated human PBLs were transfected with 200 pmol of siRNA oligonucleotides specific for the target protein (Stealth Select siRNA; Life Technologies, Carlsbad, CA) or a non-specific control oligo (Life Technologies, Carlsbad, CA). Transient transfections were performed using Amaxa nucleofactor kits for human T cells (Lonza, Basel, Switzerland) and the Amaxa Nucleofector II or 4D systems (programmes T-20 or EI-115). Cells were cultured in IL-2 (100 IU/mL) for four days to allow target gene knockdown. Knockdown efficiency was periodically evaluated by Western blotting.

Non-specific Stealth RNAi Negative Control Duplexes (12935-300, Life Technologies, Carlsbad, CA) were used as a negative control.

siRNA SAP: sense strand UGUACUGCCUAUGUGUGCUGUAUCA, antisense strand UGAUACAGCAGACAUAGGCAGUACA.

To test restimulation induced cell death, activated T cells (10⁵ cells/well) were plated in triplicate in 96-well round-bottom plate and treated with anti-CD3 (clone OKT3) (10 ng/mL) in RPMI-GlutaMAX supplemented with 100 IU/mL rhIL-2 for 24 h. In these assays, inhibitors (10 µM) were added 30 min before the restimulation with OKT3. 24 h after treatment, cells were stained with 20 ng/mL propidium iodide and collected for a constant time of 30 s per sample on Attune Nxt Flow Cytometer (Thermo Fisher Scientific, Waltham, MA). Cell death is expressed as % cell loss and calculated as:

$$\% \text{ cell loss} = \left(1 - \left(\frac{\text{number of viable cells in sample}}{\text{number of viable cells in control}} \right) \times 100 \right)$$

Results were expressed as mean ± standard error of the mean (SEM). We always compared controls and SAP silenced lymphocytes from the same donors as there is a large individual variability in RICD sensitivity.

2.9. Migration assays

Cell migration assays were performed using the Culture-Insert 2 well in µ-Dish (ibidi GmbH, Martinsried, Germany).

Briefly, 25,000 MCF7 cells were plated in each well and cultured for 24 h. The day after, the culture insert was removed and the cells were washed with PBS before treating them with respective DGK α inhibitors (10 µM) or DMSO for 15 h in complete medium (DMEM 10% FBS + 1% penicillin/streptomycin), while medium without FBS was used as a negative control for migration.

Phase-contrast pictures were taken immediately after treatment (0 h) and after 15 h under 5× magnification.

Finally, wound areas were determined using ImageJ software (NIH, Bethesda, MD). Wound reduction was calculated by using the following formula: (wound area at 15 h/wound area at 0 h)×100, the values obtained were expressed as the percentage of wound area compared to the initial area.

2.10. Quantification and statistical analysis

Data for the screen on OST-DGK α homogenates are the mean of duplicates. The compounds showing inhibitory activity in this assay were tested >4 times and the mean \pm SEM is reported.

To calculate IC₅₀ values of active inhibitors, the inhibitor activity was measured at least three times at 0.1, 1.0, 10.0, and 100.0 μ M concentration. Data were analysed using [inhibitor] vs. normalised response parameters with least square [ordinary] curve fitting method in GraphPad PRISM 8.0 software (GraphPad Software, La Jolla, CA) mentioning 95% confidence interval and IC₅₀ values always greater than 0.0. Graph shows the mean \pm SEM of inhibitor activity at the indicated concentration. In all the experiments, the data were normalised with the controls.

Evaluation of *in vitro* assays across multiple treatments (RICD), SOD-sensitive CytC reduction assay, migration assays were

analysed by using one-way ANOVA with multiple comparisons correction using GraphPad PRISM 8.0 software (GraphPad Software, La Jolla, CA). Error bars are described in figure legends as \pm SEM or \pm SD where appropriate. A single, double, triple and four asterisk denotes significance of a *p* value \leq 0.05, \leq 0.01, \leq 0.001, and \leq 0.0001 respectively in all experiments.

2.11. Pharmacophoric model

A representative 3D structure of each compound was generated using OMEGA2 software^{34–36}. The generated file was used to generate a pharmacophore model with the Pharmagist web server (bioinfo3d.cs.tau.ac.il/PharmaGist/)³⁷.

3. Results

3.1. Chemistry

At the beginning, we purchased 14 analogues of Amb639752 by vendors (Figure 3), while one analogue (2), being not commercially available, was synthesised (see Supplementary material). All the compounds were evaluated for their inhibitory activity on DGK α at a concentration of 100 μ M (Table 1).

Figure 3. First set of compounds tested for their inhibitory activity on DGK α .

Each inhibitor was tested in duplicate at least once, and DGK α activity was expressed as percentage of residual DGK α activity compared to DMSO control in the same assay. Assay uses OST-DGK α overexpressing cell lysates in presence of saturating exogenous DAG and ATP. We considered R59022 (commercially available) and the lead compound Amb63975230 as our reference molecules. As expected, our reference inhibitors R59022 and Amb639752 featured 73% and 96% inhibition respectively, confirming the quality of data obtained.

This first screening showed us how Amb639752 exhibits a rigid structure activity relationship. Indeed, both the methyl groups on the 2,6 position of indole are mandatory, the NH indole cannot be alkylated as well as ramifications on the alkyl chain are detrimental. We then focussed our attention on furan ring knowing its intrinsic toxicity via metabolic activation³⁸. Unfortunately, there were no analogues available by vendors. Our first goal was to replace the furan moiety with the phenyl ring, investigating two different synthetic pathways.

Table 1. Inhibitory activity on DGK α (I).

Compound	Residue activity at 100 μ M
R59022	27
R59949	28
Amb639752	4
Amb758897	67
Amb37496	114
Amb626577	127
Amb1926062	88
Amb94966	196
Amb730692	45
Amb98433	81
Amb18718	135
Amb726054	126
Amb731111	130
Amb22018852	160
Amb687392	115
Amb758592	150
Amb629700	101
2	135

In the first one, the commercially available 2,6-dimethyl-1H-indole **3** was acylated with 2-chloroacetyl chloride **4**, in the presence of DBU in dichloroethane³⁹ to give the derivative **5** 90% yield. Then, the acylated compound **5** was reacted with *N*-Boc piperazine in the presence of potassium carbonate and potassium iodide to afford the piperazinic derivative **6** in 63% yield. Boc deprotection with trifluoroacetic acid, followed by coupling with benzoic acid using the condensing agent EDCI afforded the final compound **8** (Scheme 1).

In the second synthetic strategy, we initially coupled the benzoic acid with *N*-Boc piperazine in the presence of EDCI to give piperazinic derivative **9** in 49% yield. Boc deprotection gave in quantitative yield the compound **10**. Due to its high aqueous solubility, solvent was evaporated and the crude as trifluoroacetate salt was directly used for the next step, where it was reacted with the acylated indole **5** to give the final compound **8** in 25% yield (Scheme 2) (see Supplementary material for full synthetic details).

Overall yield calculation was 11% for both strategies, but with the first route it was possible to use a common synthetic intermediate **7** which can be coupled with different carboxylic acids. Furthermore, the second route requires more purification steps. For this reason, we applied the first route and coupled the advanced intermediate **7** with 12 different carboxylic acids (Figure 4) to afford compounds **11–22** (Figure 5).

All those molecules were dissolved in DMSO and tested at a concentration of 100 μ M for the ability to inhibit DGK α using equal amounts of DMSO as control. We identified eight compounds capable of reducing OST-DGK α activity similar or superior to R59022 (Table 2).

3.2. Potency and isoform specificity of active molecules

To measure the inhibitor potency, we determined the IC₅₀ values for the compounds that resulted active when tested at 100 μ M by measuring the residual OST-DGK α activity over a dose range of inhibitor concentrations (0.1 μ M, 1.0 μ M, 10.0 μ M, and 100.0 μ M).

Scheme 1. The first synthetic route for the compound **8**.

Scheme 2. The second synthetic route for the compound **8**.

Figure 4. Carboxylic acids used.

For R59022 and Amb639752, we measured IC_{50} values of $15.2 \pm 5.8 \mu\text{M}$ and $6.9 \pm 3.0 \mu\text{M}$ respectively which were comparable to previous reports using similar assay conditions⁹. Considering those two as reference/template compounds, we measured the IC_{50} values of **8**, **11**, **12**, **13**, **14**, **16**, **19**, and **20** as 3.2 ± 1.0 , 1.6 ± 0.4 , 3.6 ± 1.2 , 6.9 ± 2.3 , 3.0 ± 1.0 , 32.8 ± 11.5 , 49.7 ± 31.7 , and $1.8 \pm 0.4 \mu\text{M}$, respectively, signifying that their activity is equal or superior to the template compounds (Figure 6).

Due to their higher IC_{50} values, we thus decided to exclude **16** and **19** for further experiments. In summary, we recognised six compounds with equal or superior inhibitory activity compared to commercially available DGK α inhibitors.

To check the isoform specificity of those active molecules, we tested them, along with Amb639752, for their ability to inhibit DGK α , DGK ζ (the other major DGK isoform expressed in lymphocytes), and the more distantly related and widely expressed DGK θ . At the highest concentration of $100 \mu\text{M}$, all those molecules resulted in highly specific against DGK α as like their parent molecule, Amb639752 by completely inhibit DGK α whereas they do not have significant effects on DGK ζ and DGK θ apart from **20** which, at the contrary, acts as an activator of DGK θ (Figure 7).

3.3. Activity of compounds on serotonin receptors

R59022, R59949, and ritanserin feature a dual activity as DGK α inhibitors and serotonin receptor antagonists²⁵. Conversely, Amb639752 was reported as a selective DGK α inhibitor which has no effects on serotonin activity⁹. Thus, we investigated whether the active molecules identified affect serotonin signalling.

To this purpose, we measured the effect of serotonin on PMA-induced oxidative burst in human monocytes. As previously shown, $1 \mu\text{M}$ serotonin reverses the oxidative burst to control values³³. Known serotonin receptor antagonists ritanserin and ketanserin ($10 \mu\text{M}$) impaired serotonin action, while pure DGK α inhibitors such as Amb639752 had no effect (Figure 8). These data indicate that this assay is sensitive to perturbations in serotonin signalling independently of activity against DGK α . Interestingly, as like Amb639752, all the newly synthesised active molecules did not affect serotonin action (Figure 8), indicating that all those molecules are not serotonin receptor antagonists.

3.4. DGK α inhibitors restore RICD in SAP deficient T cells

Ruffo et al. demonstrated that the defective RICD observed in T cells from XLP-1 patients was rescued by silencing DGK α expression or by pre-treatment with DGK α inhibitors R59949 or R59022⁸. Interestingly, R59022 also showed beneficial effects in an *in vivo* model of XLP-1, but due to its poor pharmacological proprieties, its use in human patients results unlikely. We therefore tested the effect all those active molecules along with Amb639752 on RICD sensitivity of SAP-deficient T cells. As additional controls, we also included ritanserin and ketanserin to evaluate the contribution of serotonin antagonism to the effects observed.

To evaluate inhibitor efficacy in physiological context, we modelled XLP-1 by silencing SAP in primary peripheral blood T lymphocytes (PBLs) and restimulating them with anti-CD3 antibody (OKT3 10 ng/mL , 24 h). We pre-treated the cells with the indicated

Figure 5. Putative DGK α inhibitors synthesised. In brackets the yield of the coupling reaction with the common intermediate 7.

inhibitors for 30 min at a concentration of $10\ \mu\text{M}$ ⁸. In control siRNA-transfected cells, DGK α inhibitors poorly affect RICD, with Amb639752, **11** and **14** slightly reducing it (Figure 9). Conversely, DGK α inhibitors significantly rescued the apoptotic defect of SAP-deficient T cells although not reaching control levels. At $10\ \mu\text{M}$, all the new molecules showed an efficacy comparable to Amb637952 and ritanserin used as positive reference molecules. Conversely, the serotonin antagonist ketanserin is inactive, excluding the involvement of serotonin receptors in rescuing the RICD in SAP-deficient T cells (Figure 9).

In summary, these data confirm that the newly identified DGK α inhibitors can rescue RICD susceptibility in T cell models of XLP-1 suggesting a putative use for XLP-1 therapy.

Table 2. Inhibitory activity on DGK α (II).

3.5. DGK α inhibitors reduce migration of the cancer cells (MCF7)

Previous studies conducted in our laboratory demonstrated that the inhibition of DGK activity decreases chemotaxis, proliferation, migration, and invasion of many cancer cell lines^{12–14}. To evaluate if our newly synthesised DGK α inhibitors were effective in

impairing cancer cell migration, we measured serum induced wound healing in MCF7 breast cancer cells in presence of 10 μ M inhibitor. In presence of serum, none of the inhibitors is toxic for MCF7 cells even after prolonged treatment (data not shown). After 15 h of treatment, all the newly synthesised active molecules

Figure 7. Isoform specificity of novel DGK α inhibitors. 293T cells were transfected with different DGK isoforms (A – DGK α , B – DGK ζ , C – DGK θ , respectively) or empty vectors and homogenised. All the molecules were tested at 100 μ M for their capacity to inhibit the DGK activity of the different isoform homogenates. Data are means \pm SEM of at least three independent experiments performed in triplicate.

Figure 8. Novel DGK α inhibitors do not affect serotonin signalling. Human monocytes were pre-incubated for 1 h with the indicated drugs in absence or presence of serotonin and then stimulated with PMA 1 μ M for 30 min (■ control unstimulated cells, □ PMA stimulated cells, ■ PMA and serotonin stimulated cells). Results are expressed as n moles of reduced cytochrome C/10⁶ cells. Data are means \pm SEM of 10 independent experiments performed in triplicate.

Figure 10. Novel DGK α inhibitors slow tumour cell migration. MCF7 monolayer was wounded and treated for 15 h with serum in presence of our new DGK α inhibitors (10 μ M) or vehicle (DMSO). Results are expressed as the percentage of wound area compared to the initial area. Data are the mean \pm SEM of nine independent experiments.

Figure 9. DGK α inhibitors partially restores apoptosis in SAP deficient lymphocytes. Lymphocytes from normal subjects were transfected with control or SAP specific siRNA (■ control siRNA, ■ SAP siRNA). After 4 days, the cells were restimulated with CD3 agonist OKT3 (10 ng/mL) in presence of respective inhibitor. Vehicle (DMSO) was used as control. Twenty-four hours later, the % of cell loss was evaluated by PI staining. Data are the mean \pm SEM of nine independent experiments performed in triplicate.

equally reduced cell migration when compared to the vehicle (DMSO) delaying wound closure (Figure 10).

Besides being in good agreement with the notion that DGK α is required for cancer cells migration, this observation indicates that our new DGK α inhibitors reduce cancer cell motility, suggesting a potential utility in a metastasis setting.

3.6. Generation of a pharmacophore hypothesis

From the data obtained, it is possible to identify some key pharmacophoric points crucial for the biological activity of the Amb compounds on DGKs namely: (i) a basic nitrogen; (ii) the methyl groups at the 2 and 6 position of the indole nucleus, and (iii) a (hetero)aromatic ring. This information allows us to build a four-point pharmacophoric model represented in Figure 11 superimposed with the minimised structure of compound 11. Although, we are not able to evaluate the importance of the two carbonyl groups, it represents the first attempts in order to identify the minimum structural request to interact with DGK catalytic site considering the molecular structure of the four most active inhibitors discovered to date (Amb639752, ritanserin, R59022, and R59949). We feel that this model might be useful to identify novel

Figure 11. Proposed pharmacophoric model.

compounds active on DGK α through more targeted virtual screening campaigns, overcoming the current scaffolds.

4. Discussion

As a key component of several signal transduction pathways, DGK α represent an emerging pharmacological target. We have demonstrated the efficacy of DGK α inhibitors for XLP-1 treatment⁸, while others have proposed them for cancer treatment²² and to remove immune-checkpoints promoting immune vigilance against cancer⁴⁰. Commercially available DGK α inhibitors are limited by poor specificity^{25,41} and pharmacokinetic²⁰. The CU-3 molecule described by other features a noteworthy activity and specificity but its reactive chemical structure make unlikely an *in vivo* use³⁰. With intent of developing molecules suitable for therapeutic use we selected Amb639752 as a novel inhibitor with remarkable DGK α activity. Amb639752 also features improved selectivity for DGK α as it does not affect serotonin signalling⁹. Despite numerous efforts a structure of mammalian DGKs is still missing, thus we decided to explore the structure–activity relationship of this molecule to improve its activity and pave the way for further developments. Our efforts allowed us to build a pharmacophoric model for DGK α inhibitors characterised by three required features. We also characterised a set of novel compounds with improved IC₅₀ in the low μ M range and identified the most profitable synthetic route for them. The mode of DGK α inhibition by those molecules is still unknown apart for ritanserin, which binds at the same time the DGK α catalytic accessory domain and the C1 domain putatively promoting a close inactive conformation⁴¹.

The second-generation inhibitors we described in this work maintain the specificity of Amb639752 as they not affect DGK ζ , the predominant isoform of lymphocytes⁴² and the broadly expressed DGK θ ⁴³. Those DGK α inhibitors are active in a lymphocyte based XLP-1 assay and in a cancer cell migration assay, holding the promise for a potential therapeutic application. However, their efficacy is still to be determined in *in vivo* models of disease where some of the parental compounds showed efficacy but poor pharmacokinetic^{8,20}.
